

Predicting U.S. Hospital Ratings with Performance Data

By: Franco Menares Paredes, Fangzhou Yuan, Xiyi(Britney) Wang, Jiangyue Zhu
 Course: 36-600, Overview of Statistical Learning and Modeling

Introduction

This study examines a range of factors affecting hospital ratings, particularly emphasizing the importance of medical costs and the implementation of safety measures. By analyzing a comprehensive dataset of American hospital evaluations, we aim to create an analytical model capable of predicting hospital ratings.

The goal of this project is to find the optimal model that accurately classifies high-rated and low-rated hospitals, directing improvements in healthcare quality and patient satisfaction.

Data

The dataset is comprised of detailed records from 1,739 hospitals across the United States. It features 20 predictive variables that inform the binary Rating response variable, which classifies hospital performance as "low" (1-3 stars) or "high" (4-5 stars). The predictors consist of both numerical and categorical variables, encompassing hospital performance metrics and costs associated with key procedures.

| Variable | Definition | Variable | Definition |
|--------------------------------|----------------------------------|---------------------------------|------------------------------|
| Facility.Type | Type of hospital | Procedure.Heart.Attack.Value | Value for heart attack care |
| Rating.Mortality | Mortality rate comparison | Procedure.Heart.Failure.Cost | Cost for heart failure care |
| Rating.Safety | Safety comparison | Procedure.Heart.Failure.Quality | Heart failure care quality |
| Rating.Readmission | Readmission rate comparison | Procedure.Heart.Failure.Value | Value for heart failure care |
| Rating.Experience | Patient experience comparison | Procedure.Pneumonia.Cost | Cost for pneumonia care |
| Rating.Effectiveness | Effectiveness of care comparison | Procedure.Pneumonia.Quality | Pneumonia care quality |
| Rating.Timeliness | Timeliness of care comparison | Procedure.Pneumonia.Value | Value for pneumonia care |
| Rating.Imaging | Use of imaging comparison | Procedure.Hip.Knee.Cost | Cost for hip/knee care |
| Procedure.Heart.Attack.Cost | Cost for heart attack care | Procedure.Hip.Knee.Quality | Hip/knee care quality |
| Procedure.Heart.Attack.Quality | Heart attack care quality | Procedure.Hip.Knee.Value | Value for hip/knee care |

Modeling Analysis

- We splitted our data so that 80% is used for training and 20% for testing.
- We develop binary classification using logistic regression, linear-kernel SVM, decision tree, random forest, and XGBoost.
- For each of these models, we generate ROC curves for each model and compute the AUC values. The model with the highest AUC will be considered the best.

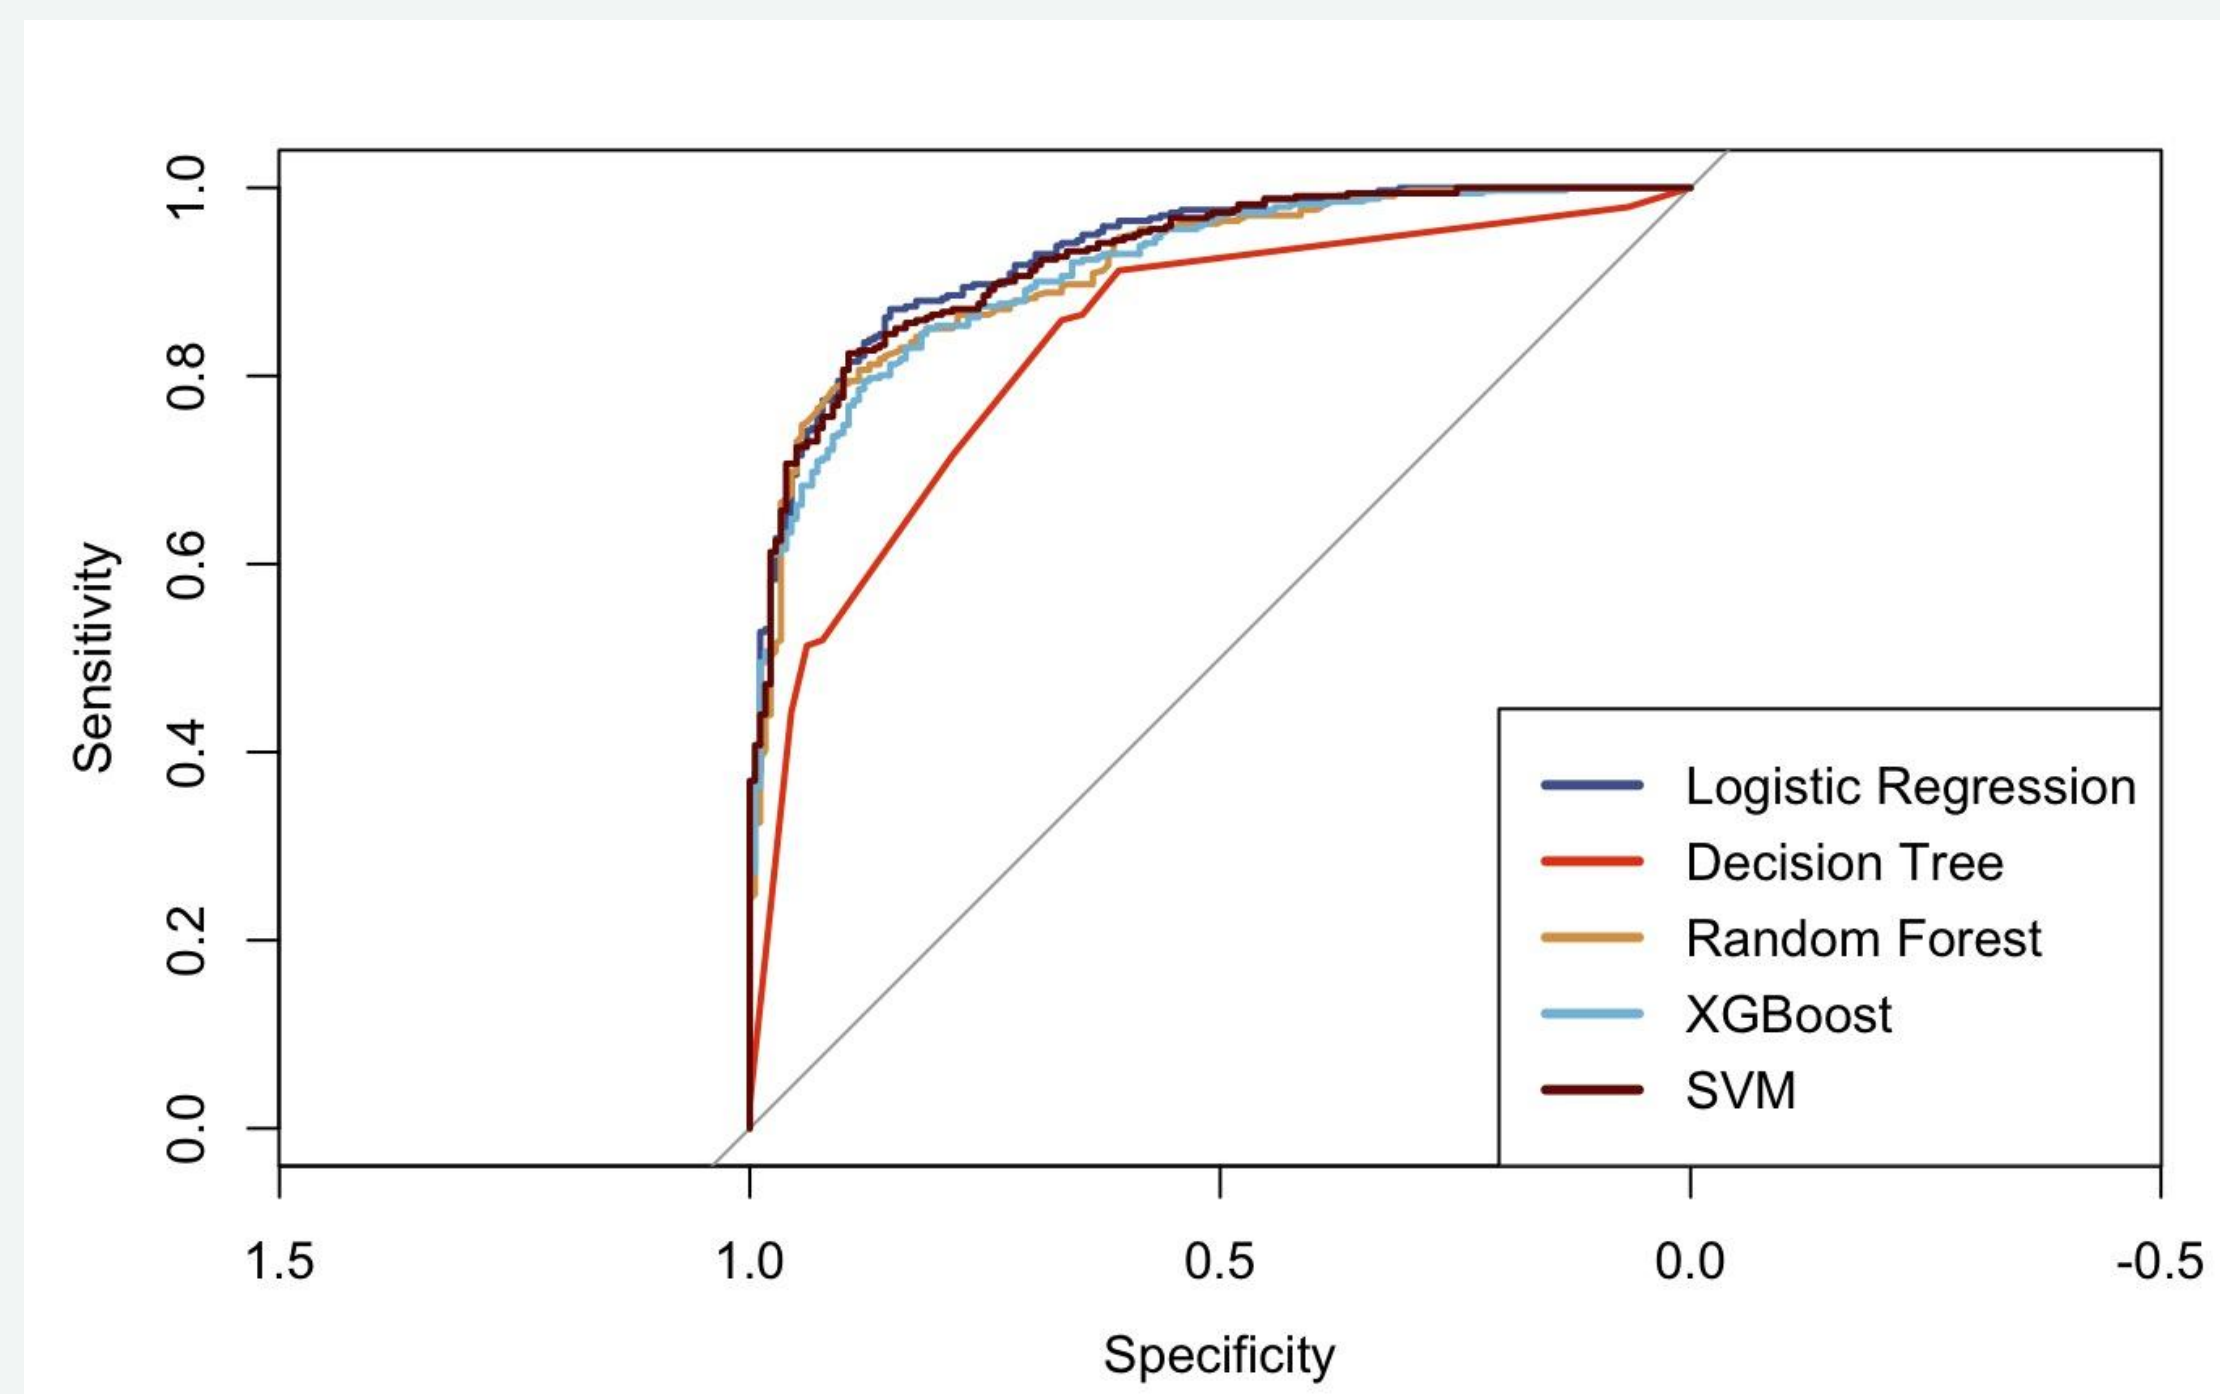

Figure 3: ROC curves of different models

| Model | Logistic Regression | SVM | Decision Tree | Random Forest | XGBoost |
|-------|---------------------|-------|---------------|---------------|---------|
| AUC | 0.930 | 0.925 | 0.835 | 0.914 | 0.912 |

Table 2: AUCs for each model

| | Response = high | Response = low |
|-------------------|-----------------|----------------|
| Prediction = high | 154 | 44 |
| Prediction = low | 27 | 297 |

Table 3: Confusion Matrix for Logistic Regression

Observations:

- The highest AUC 0.930 is from logistic regression model. The optimum threshold is 0.581, MCR is 0.136.
- Optimal class separations for all models are generated by maximizing Youden's J statistic, hence balancing the classification results and make better predictions for the class with a smaller sample size
- Rating.Experience, Rating.Safety, Rating.Readmission have the highest importance, followed by Rating.Mortality, Procedure.Hip.Knee.Cost, Procedure.Pneumonia.Quality, etc. Therefore, patient experience, hospital safety and readmission are most crucial for hospital ratings.

Conclusion

Our analysis successfully applied various predictive models to determine the best approach for classifying U.S. hospitals into "high" and "low" rating categories based on a range of performance metrics. The logistic regression model demonstrated the highest efficiency with an AUC of 0.930, indicating a strong predictive capability.

This study lays the groundwork for future research where these models can be further refined and potentially applied in real-world scenarios to guide improvements in healthcare quality and patient satisfaction. Future analysis may focus on integrating additional variables, exploring alternative modeling techniques, or applying the model to different subsets of the healthcare system.
