

Carnegie Mellon Undergraduate Alumnus Prospects After Graduation

Je Woo Sun, Erika Tang, and David Zimmerman

This study delves into the intricacies of university rankings to uncover the accuracy with which Carnegie Mellon University reports the success of its undergraduate alumnus.

Introduction

Motivation

Given the recent scandal revealing the over optimistic prospects for graduating law school students, the statistics produced by universities and published in the US News and World Report are being brought into question. These misleading statistics encourage hopeful JD seekers to pursue startling loans with the expectation that their debts will be paid off with relative ease upon graduation thanks to supposed 84% job placement ratings.

While the production of undergraduate college rankings has often been criticized for its accuracy in measuring the actual quality of education, Carnegie Mellon University and other universities have long bolstered their reputations for producing intelligent, motivated, and successful students with the use of these faulty lists. However, this raises the question of how measurably successful Carnegie Mellon University undergraduate alumni are. Where do alumni relocate? What occupations do they practice? What graduate programs do they choose to pursue? And, according to the common man's perception of comparative success, how do Carnegie Mellon University undergraduate alumni measure up when compared to graduates of other universities?

Past Literature

Others have conducted analyses of the correlation between academic quality and university ranking systems such as David D. Dill's and Maarja Soo's "Academic quality, league tables, and public policy: A cross-national analysis of university ranking systems" published by "Higher Education," "International University Ranking Systems and the Idea of University Excellence" by Paul Taylor and Richard Braddock from the "Journal of Higher Education Policy and Management," and College Rankings Exposed: the Art of Getting a Quality Education in the 21st Century by Paul Boyer. Each of these articles and the book discusses the concept of ranking systems as a measure of excellence, but no study has directly applied these concepts of ranking as excellence to Carnegie Mellon University.

Summary of Procedure and Results

This study analyzes the data collected and evaluated by the Carnegie Mellon University Career Center (http://www.studentaffairs.cmu.edu/career/students_alumni/post-grad-survey/index.html) in order to answer such questions as: Are alumni—successful by Carnegie Mellon standards—well received by employers and graduate programs? Do alumni display a tendency to remain near to Pittsburgh or to relocate elsewhere? Do alumni successfully attain employment relevant to their subject(s) of study? How accurately do national and international rankings systems gauge the value of a Carnegie Mellon Undergraduate degree?

The data collected from the Carnegie Mellon University Career Center is will also be used to test the effectiveness of various survey methods. The Career Center has nearly perfected its collection data collection methods as response rates generally run somewhere in the 90th percentile (with the exception of College of Fine Arts classes where response rates are as low as the 70th percentile). This has yielded results near to that of census data. As such, this study assesses the effectiveness of certain types of sampling schemes (stratified and clustered sampling) to produce results representative of the target population so that future statistical researchers can visually apprehend the significance of various survey designs. Few have had the data provided or the opportunity to conduct a study on accurate census data in order to optimize survey results to population parameters.

Operating under the assumption that that the processes of data compilation—including the garnering of data from outside sources and the biases that potentially arise from human coding—results from this study indicate that the overwhelming majority of graduated alumnus from

Carnegie Mellon University's undergraduate program attain employment that is relevant to their concentration of study. The results reflect similarly positive outcomes for students enrolling in graduate school; the average Carnegie Mellon University undergraduate alumnus attends a graduate program more prestigious than the equivalent graduate program offered by Carnegie Mellon University. However, contrary to current Carnegie Mellon University undergraduate perception, variation across schools for all of the tested variables was negligent; salary, prestige of graduate program, and distance from Pittsburgh did not vary significantly among colleges. Rather, variation—for all variables—was much larger between majors within a given college. We ran ANOVA test on all possible combination of variables. Three response variables were salary, miles from Pittsburgh, and comparative ranking. Three explanatory variables were school (college), major, and year. The results show that all three response variables' means were different across school and major. As for year variable, salary was the only response variable whose mean differed at 3 year period. Then we ran 2 regression analyses on our quantitative variables. They were miles from Pittsburgh versus Salary and miles from Pittsburgh versus comparative ranking. The former was statistically insignificant while the latter was statistically significant. However, the coefficient for the second test was too small for us to conclude anything of scientific interest.

Methods

Population and Sample

Our target population was graduating Carnegie Mellon undergraduates of the Pittsburgh campus from the years 2008 to 2010. The sampling frame that came with this data originated from the career center's post graduation survey. This data from the Career Center consistently includes greater than 94%-71% response rates. Majors within CFA had the lowest set of response rates. This may be due to the significantly smaller class sizes, the personalities of the students, and the difficulties associated with categorizing employment in the arts. With the administrative records from the career center we attempted to reconstruct the entire graduating classes from 2008-2010. Each person who answered the survey and either was employed or went on to graduate school was listed individually. For the employed graduates the company name, job title, and location of job by city and state were given. At times these jobs were not in the United States and therefore had a name and country, a country, or just a city. Those who went on to graduate school were listed by university, by specific program, and then whether they were getting a Masters or PhD degree. From these individual listings we were able to create a spreadsheet that contained each individual from the post-graduation survey.

Our sample design consisted of two very different approaches. Based on the wealth of information provided by the Career Center we were able to construct a sampling frame that was almost exactly the same as the target population. This allowed us to conduct tests on essentially the data from the whole population, which would make our study a census. We then did a second round of analysis where we used various types of sampling methods. The first time did a simple random sample of the students in each year. We took 2008 through 2010 and took simple random samples each one. This was then combined to calculate all of our inference tests. In each year we took various sizes of samples. Based on our calculations that come later we found the ideal sample size per year to be 292 students. In a discussion with Professor Junker we examined the idea of using various sizes of simple random samples and compare them to the census data we had. Our sample sizes ended up being 100, 300, 600, and 900 students from a single year. Delete This Section (We then stratified the data and broke all of the students into the six colleges that are part of the university: the College of Fine Arts (CFA), Carnegie Institute of Technology (CIT), the College of Humanities and Social Sciences (HSS), the Mellon College of Science (MCS), the School of Computer

Science (SCS), and the Tepper School of Business (Tepper). From there we stratified the data again and took each department in the school and pulled a random sample from each of those. Our next method involved stratifying the data by college again and then using each department as a cluster. From there we randomly picked on cluster or department in each school and sampled every single student in those clusters. Based on the clustered and stratified by department example we will test these results with the census data to see how accurate these prediction methods are for our study.)

Sample Size Calculations Without Replacement

$$n > \frac{N \cdot n_o}{N + n_o}$$

$$n_o = \frac{z^2 \cdot SD^2}{ME^2}, z = 1.96$$

$$n_o = \frac{1.96^2 \cdot 0.5^2}{0.05^2} = 384.16$$

$$n = 292$$

$SD = 0.5, ME = 0.05, N = 1200$ (estimate)

set up to do FPC but didn't actually do it?

We do not have any sort of data on the variance of the six colleges when it comes to our most important question: the percentage of Carnegie Mellon Undergraduates who gain employment in a workplace that utilizes the knowledge and skills they learned as a result of their particular major, it is very difficult to calculate any kind of sample size estimate using stratification. Unless the groups are significantly different there will be no gain from stratifying in the sample size calculations.

We used the data of about 3600 individual students. About each year 1200 students graduate and we have 3 years worth of responses. Our nonresponse rate was based purely on the ability of the Career Center to collect responses from individuals. As stated previously the numbers that they provide are fairly good. We will attempt to use imputation when we run into individuals that do not respond. This will make it so when we actually select our samples from the frame there will be no nonresponse. Our information is limited to what the Career Center will give us. In order to increase the variables that we have we are matching the information we have to external databases. We will be using <http://www.indeed.com> to add in salary information based on the job title. With the aid of *US News* and *Fiske* we will get information about the rankings of college graduate programs. Some of the summary sheets from the Career center have aggregate information about salaries so we will use that to check our additional data from indeed.com.

Variables

Since we are looking at administrative records our questionnaire is a list of variables that we will look for when examining an individual. The primary ones include salary in present dollars, the distance the graduates end up from Pittsburgh, PA, whether the current job they have requires or uses the knowledge and skills learned in undergraduate study, the ranking of the graduate program relative to Carnegie Mellon's ranking in that area, and whether the student is employed.

For the percentage of CMU students that find jobs we are recording anyone who has a job title and/or employer as a person that is considered employed. Some of the data only had an employer or only a job title so we included them in the category of being employed. One tricky aspect to this variable is that CFA has a number of students who listed themselves as freelance. This is somewhat difficult because the nature of some professions. Often the acting sector does not follow the traditional method of employment because it only lasts as long as the production which can be several months instead of years like most other jobs. There are a few individuals not in CFA who consider themselves as self-employed. We counted all of these people as employed, which is one

reason why the CFA employment figures may be inflated. We included any military positions and volunteer positions in the employed category.

Next we looked at all of the individuals from each college in order to compare the proportions of employment across the colleges. We also separated our sample by year in order to see how much the employment proportions changed over the three years we have data on. Finally we calculated the employment rates of each college in order to compare how the majors differed in employment rates.

Our post survey processing is the entering of the data from the Career Center sheets to an excel file. We will have multiple people go through to check whether they think that the job description matches the major. Since the titles can be very ambiguous we were hoping to look at the ones where we did not agree.

We looked at the percentage of people who ended up in each state/country. In our data file there was one column for city and one column for state or country. All of the employed positions had locations attached with them so we just used those. For the students attending graduate school we assumed that they lived in or near the city that the campus was in.

Our variable for higher education included all individuals attending or planning to attend a university or college. For most individuals this was fairly straight forward because they had a name for the institution and listed the program they would be participating in. There were a number of individuals that said they would be going to medical school or law school, but failed to specify beyond this. We considered these individuals as students attending graduate school.

The comparative rankings variable consists of several parts. First we looked at the program in which the student was enrolled. From there we looked up the USNews graduate school ranking for that program at the college where the individual was attending and at CMU. This was used in order to see the differences between the institutions that CMU students attend relative to the level at which they already are enrolled. Our final variable was the comparative ranking, which consisted of the CMU ranking minus the ranking of the other school. This would allow us to take the mean of the variable and see on average whether graduates were going to more or less prestigious universities relative to CMU. When a university was not ranked or did not have that program we considered them to have rank 100 in order to show that the difference in rankings is significant and also allow us calculate the statistics for each individual.

One interesting fact we wanted to explore was the relationship between major and change in comparative ranking. Calculated this variable as the mean of the comparative rankings for each major and then put them into an ordered table with the major that has the largest increase in comparative ranking at the top.

For the percentage of graduate students remaining at CMU we looked at the total number graduate students and the number of those going to CMU for graduate school. This does not include people who are hired as research assistants and have an employer of CMU. We then took the number of graduate students attending CMU divided by the total number of graduate students.

From there we made a table of all graduate degrees with the frequency in which they occurred and the percentage of all the degrees. Given how specific some of the students were it may skew the results because degrees may be very similar but are not counted as exactly the same degree because of slight differences. We ranked the table so that those with the highest frequency were listed on top and included the top 10 majors graduates pursue.

Indeed.com was our source for salary information. It allowed for the specification of job title employer and city. With this information it would give back an estimated salary for the given criteria. Since our job titles were fairly vague and sometimes the website would not return any valid results there was some estimation on our part on what some individuals' jobs could be simplified to. A number of the jobs included very ambiguous titles and we were unable to use very specific information to find an estimated salary. One aspect is that we were not able to specify that these should be starting salaries and therefore this may include a somewhat bias sample.

From this data we estimated the mean salaries for the total sample, each year, each college, and each major. This allowed us to test which ones were different and how they compared overall.

Our last variable was the percentage of students who decided to remain in Pittsburgh for education or work. We included all individuals who attended CMU as well as any other Pittsburgh Universities. This was then divided by the total number of people in our sample to get the percentage who remained in Pittsburgh. This variable is intended to capture some information possibly about how willing or able people are to remain here after spending about four to five years in the city.

We did not have access to the original sample so the possibility of collecting responses from those individuals who already graduated was not an angle we tried. Based on the results from the career center it seems that for the older data, pre 2010, there are some facts that are missing and would help in the creation of a full sampling frame. The specific information about how many people returned to their home countries and how many non-responders occurred in each major would have greatly increased our ability to narrow down the statistics that have non-response bias. We did not have any demographic information on the individuals so post stratification was not a reasonable choice of action. The percentage of responders that we had access to relative to the whole graduating class was very high.

We decided that since our sampling frame covered about 80% of the population we would try sampling from the data set we had in order to see how various sample sizes did at estimating various statistics. Here we essentially considered the data set from the career center as our population data and then took simple random samples from the whole set in various sizes. Based on our calculations we would need about 300 people from a single year. In order to test the just how close the various sample sizes were at estimating the assumed population means and proportions. We used samples of 300, 900, 1800, and 2700 from the population. By pooling all of the years together we made it just a simple random sample instead of having clusters or strata. Using 300 for n was supposed to provide an example of a sample size that is much too small to achieve our desired results of a 95% confidence with a margin of error of .05. The 900-person sample was intended to be just about right and the other two should be much more than is necessary.

Results

Based on the current events around the graduate school employment and how they have come into question, we are looking at the employment rates and the correlation between jobs and majors. This will be used to tell whether the skills that a CMU student learns from their expensive education are utilized throughout their working experience in the real world. In order to determine whether the high price of CMU is worthwhile we are looking at the mean salary incomes of graduates to see if they end up making sufficient sums of money that would allow them to make up the difference in tuition from CMU to a public university.

We also chose to look at how CMU students fared when attempting to get into graduate school. Our plan was to look up the rankings of programs that graduates attend and see if they are moving up in the world when it comes to rankings by USNews or not. This allowed us to look at what majors sent people to graduate schools that were ranked higher or lower than the CMU ranking.

Lastly our survey looked into the various places that graduates ended up. We are looking for the distances from Pittsburgh to the new location where people reside. This is supposed to demonstrate how far CMU graduates go and where they end up in the end.

Through the analysis of data obtained through the Carnegie Mellon University Career Center, this study hopes to report the accuracy with which the university publishes positive

statistics concerning the successes of undergraduate alumnus. This study also aims to delve deeper than any large ranking system can hope by analyzing the implications of enrollment within specific colleges and majors within Carnegie Mellon University; are there significant statistical differences between the ability of students from different majors of colleges to obtain jobs or matriculate in more prestigious graduate programs.

In order to test the various sample sizes for a simple random sample we used SPSS in order to pull 300, 900, 1800, and 2700 random people from our sampling frame of 3311. Each of these simple random samples was placed in their own data file and then we conducted tests on them separately. The method we used for comparing the SRS's to the population figures was a one-sample t-test. Here we compared the means or proportions for each of the selected variables. We compared the percentage of employment, total and by each college; the percentage of correlation between major and job title; the mean salary; and the percentage of graduates that are remaining in Pittsburgh for further school or work. We were looking for statistically significant results where the null hypothesis was that the sample mean equals the population mean. Our population figures came from the sampling frame that we constructed from the 3311 entries.

All of the results can be found in the appendix of the various tests that we conducted. The printouts are from and SPSS t-test of comparing means. For percent employed we found that all four sample sizes were statistically different from the population means. When we broke down each sample with the select cases function in SPSS by college we found all of the tests to not be statistically significant. The only test that came close was the SRS of 300 individuals for the Tepper School of Business. The test had a p-value of .056.

We then proceeded to test the percent the correlation between major and job title as determined by us. Using a one-sample t-test in SPSS we found that all of the correlations between major and job title were all not statistically significant.

Next we chose the mean salary for analysis and conducted four t-tests with the different sample sizes. The null hypothesis was that the sample mean equals the population mean. We had no statistically significant results from these tests.

As for the people remaining in Pittsburgh we calculated a new variable that included only whether the individual remained in Pittsburgh after graduation or not. Our t-tests had the null hypothesis where the sample mean equals the population mean. In this set of tests we found no statistically significant results.

For all of the tests there is a general trend where the standard deviation for the samples tends to decrease as the sample size increases. This is not a universal trend, however it shows up as a general trend throughout all of the t-tests that we ran.

One-Way Anova: Salary versus School

given the large (population) N, most results should be significant. so anything *in*significant is really remarkable and worth thinking about...

Our first test was to see if salary is same across all colleges. With p-value of 0.000, we rejected the null hypothesis that mean salary is same between different colleges. School of Computer Science showed highest mean salary of \$89809 whereas College of Fine Arts had lowest mean salary of \$60831. As for other schools, they were relatively in close range of each other. The results were expected because Computer Science is more practical area of study that is in high demand right now.

One-Way ANOVA: Salary versus Major

This test is similar to ANOVA test for Salary versus School but we decided to run the Salary versus Major test more in-depth to see if we can see any anomaly. With p-value of 0.000, we rejected the null hypothesis that mean salary is same across majors. Physics had the highest mean salary of \$96367 whereas BXA had lowest mean salary of \$36915. This result was surprising because we didn't expect Physics to come out highest. It is most likely that because the website we

used for salary calculation (www.indeed.com) does not take years of job experience into account, the salary for Physics could have been overly inflated compared to other majors.

One-Way ANOVA: Salary versus Year

We also ran ANOVA test for Salary versus Year to see if mean salary stayed constant between these three years period. The p-value was 0.045 which was less than our confidence level of 0.05 so we rejected the null hypothesis that mean salary was same in year 2008, 2009, and 2010. With year 2009 mean salary being highest at \$75519, we hypothesized that there was some economic event in 2009 that caused the 2009 salary to rise.

One-Way ANOVA: Miles from Pittsburgh versus School

We decided to test if colleges had any effect on how far students end up being away from Pittsburgh after graduating. The p-value was 0.000, so we rejected null hypothesis that mean miles from Pittsburgh is same across different schools. School of Computer Science had highest mean of 1217 miles. We hypothesized that there are not many employment opportunities related to Computer Science near Pittsburgh so that is why students had to travel far to get employed.

One-Way ANOVA: Miles from Pittsburgh versus Major

We ran the test similar to the one before by breaking the colleges into majors. The p-value was 0.000 so we rejected the null hypothesis that mean miles from Pittsburgh is same across different majors. While most majors were within close range of each other, there were two majors that stood out from the rest. One was Modern Language with mean of 2881 miles and the other was Global Politics with mean of 1980 miles. This result was self-explanatory since people who majored in Modern Language and Global Politics would probably have to go abroad to make full use of their major.

One-Way ANOVA: Miles from Pittsburgh versus Year

We were curious to see if years had any effect on mean miles from Pittsburgh so we ran ANOVA test. The p-value was 0.244 which is greater than significance level of 0.05 so we retained null hypothesis that mean miles from Pittsburgh is same for 3 year period.

One-Way ANOVA: Comparative Ranking versus School

We wanted to see if different colleges had any effect on whether students went to better graduate school than that of CMU ranking-wise. The p-value was 0.000 so we rejected the null hypothesis that mean comparative ranking is same across colleges. Students from Tepper Business School had highest mean of 13.00, meaning on average, students from Tepper went to graduate school that is ranking 13 higher than that of CMU. School of Computer Science had lowest mean of -7.73, which is probably because the ranking of CMU graduate school is so high that it is hard for students to go to better school.

One-Way ANOVA: Comparative Ranking versus Major

To look at effect of student's field of study on comparative ranking more specifically, we ran the ANOVA test for comparative ranking versus major. The p-value was 0.000 so we rejected the null hypothesis that mean comparative ranking is same across majors. There was not one major that really stood out from the rest other than Policy and Management, which had lowest mean of -43.00. Just like test before, we hypothesized that Heinz School (CMU's graduate school for Policy and Management) could have been quite highly ranked compared to other graduate schools.

One-Way ANOVA: Comparative Ranking versus Year

This was the last ANOVA test we ran on population to see if years had any effect on comparative ranking. The p-value was 0.218 so we retained null hypothesis that the mean comparative ranking was same for the 3 year period.

Regression Analysis: Salary versus Miles from Pittsburgh

To see if there was any relationship between salary and how many miles students ended up being away from Pittsburgh, we ran regression analysis on these two variables. The p-value was 0.168 which was greater than confidence level of 0.05 so we retained the null hypothesis that there is no linear correlation between salary and miles from Pittsburgh.

Regression Analysis: Comparative Ranking versus Miles from Pittsburgh

To see if there are any relationship between miles from Pittsburgh and comparative ranking, we ran regression test. The p-value was 0.016 so we rejected null hypothesis that there is no linear correlation between miles from Pittsburgh and comparative ranking. At 0 mile from Pittsburgh the comparative ranking is at 5.715 and for every mile away from Pittsburgh there is a decrease of 0.002414 in comparative ranking, meaning that the further graduate schools are away from Pittsburgh, lower are their ranking. The result was surprising but at the same time, the coefficient was not that big enough for us to definitely conclude that graduate schools are ranked lower if they are further away from Pittsburgh.

Discussion

For this survey, we are trying to show CMU undergraduate prospects after they graduate so students can exactly know what awaits them once they graduate. We did not design the actual survey. There is an annual survey that Carnegie Mellon Career Center conducts on undergraduates who are graduating Carnegie Mellon University. The purpose of Career Center's survey is to keep record of undergraduate prospects after graduation such as where they are employed, their job title, salary, and whether they are going to graduate school. Our project was to take this data and analyze it further using different survey methods while adding our own variables. These new variables include correlation between one's job title and his major, the distance of one's employment place from Pittsburgh, whether the graduate school a student has enrolled is more/less prestigious than that of Carnegie Mellon using US News Ranking and Fiske for Fine Arts school.

In order to test the differences between the population and what we got for the simple random samples we conducted a series of t-tests. These served to show how far off the estimates of the various sample sizes were from the assumed population mean or proportion. The first variable that we analyzed was the proportion of Carnegie Mellon graduates that were employed out of everyone. In this case all four sample sizes were statistically different than the mean. This is quite unusual seeing as a SRS of 2700 and 1800 turned up a statistically significant different than a population that only includes 3311 people. Since we were using a significance level of .05 it is possible that each of these are fall into that 5% window of type I error. This is not very likely but it is possible that the first test is actually different and the other three just happen to have samples that appear different. In order to stretch the sampling a little more we selected only cases from specific colleges. We used the percents of employed persons and for the six colleges and only one of the t-tests was significant. The smallest sample size for Tepper was almost statistically significant at $p = .056$. This is somewhat unexpected. Based on how small the samples sizes got it would make more sense that the lowest sample sizes would have a lower chance of estimating the population figures as well. The lowest sample sizes should have higher standard deviations so they are can be

farther from the population and still not be statistically significant and that may have contributed to this.

For the remaining t-tests comparing population figures to the sample means there were no statistically significant tests. None of the tests were close to being statistically significant as well. The other variables that we used to compare sample estimates to population figures were percent for major correlating to job, mean salary, and percent of graduates that were remaining in Pittsburgh for work or school related reasons.

In general we expected there to be a number of t-tests to come up as statistically significant, especially as the sample size decreased. The fact that only one out of nine sets of tests showed even a glimmer of this trend is surprising.

Study Attributes

Strengths

Some of the strengths of this project are very high response rate and the fact that we were able to save lot of time by skipping the part where we actually conduct the survey meaning that we are able to allot more time to analysis of the data. Because we used data from Career Center, we were able to acquire data with response rate of over 90% in most cases with an exception of couple 70%'s, which is still considered very high. Because Career Center conducts this survey on every undergraduate student who is graduating, we can be confident that there is very little sampling error.

Weaknesses

However, there are also many critical flaws in our project that stems from the fact that we used Career Center's survey. One of them is that because we are not the one who designed the actual survey we are restricted to what kind of analysis we can do; we cannot tweak the survey questions to get better data that will suit our analysis purpose better. Second flaw is that Career Center did not disclose all the data to us. We do not know the exact individual's salary; we only know the min, max, and average of students' salaries grouped by year and major. As a result, we decided to get approximate salary amount from indeed.com but given that the many job titles are ambiguous, it is inevitable that we will have much error.

We are still in process of compiling the data from Career Center into Excel for more efficient analysis. Once data compilation is done we will start our analysis and will be able to find out if there are relationships between various variables and whether the employment rate that CMU has provided us is accurate and true.

Questionnaire

Variables measured by the “Carnegie Mellon Undergraduate Alumnus Prospects After Graduation” Study:

1. Percentage of CMU alumni who find employment upon graduation (for whole sample and each of five sample years)
 - a. This variable would be calculated using the Career Center data on salary as a reference

Percentage of CMU Alumni that find Job			
	Count	Total	Percent
Total	1382	3311	41.74%
2008	376	1032	36.43%
2009	505	1149	43.95%
2010	501	1130	44.34%

2. Percentage of CMU alumni from each college finding employment upon graduation (for each of three sample years)

- a. This variable would be calculated using the Career Center data on employment percentages as a reference

Percentage of CMU Alumni that find Job by College			
	Count	Total	Percent
CIT	523	1084	48.25%
CFA	403	521	77.35%
HSS	326	536	60.82%
MCS	221	574	38.5%
SCS	274	347	78.96%
TEP	219	249	87.95%

3. Percentage of CMU alumni from each major finding employment upon graduation (for whole sample and each of five sample years)

- a. This variable would be calculated using the Career Center data on employment percentages as a reference

major * employed Crosstabulation

	Economics/Statistics	13	30	43
	Global Politics	9	7	16
Total		1345	1966	3311

4. Percentage of CMU alumni whose employment relates to their major (for whole sample and each of five sample years)

- a. This variable would be calculated using the Career Center data on employer and job title
- b. Both employer and job title of each alumnus will be coded as “does relate to major” or “does not relate to major”
 - i. For a job to be coded as “does relate to major” the job title should indicate that the undergraduate degree received is necessary to fulfill some aspect of the job qualifications
 1. E.g. the job title “Mechanical Designer Engineer” does relate to a major in engineering/physics
 - ii. Coding will be conducted by several Group H members to ensure that coding is consistent by person

Year * job-major correlation (yes=1, no=0) Cross tabulation				
Count				
		Job-major correlation (yes=1, no=0)		Total
		0	1	
Year	2008	67	598	665
	2009	71	579	650
	2010	57	477	534
Total		195	1654	1849

*Note almost all people end up with job/path that is suitable for CMU

5. Percentage of CMU alumni enrolling in graduate school

- a. This variable would be calculated using the Career Center data on the number of alumnus pursuing graduate degrees in respect to his/her class

Percentages Enrolling in Graduate School			
	Count	Total	Percentage
Total	1968	3311	59.44%
2008	647	1130	57.25%
2009	654	1149	56.91%
2010	667	1032	64.63%

Percentage of Graduates Enrolling in Graduate School

6. Average comparative ranking of graduate school program compared to CMU ranking
 - a. This variable would be a measurement of the deviation from CMU ranking for each graduate program pursued by CMU alumni
 - b. Graduate program ranking would be measured as a negative or positive number in comparison with CMU ranking
 - i. Graduate program ranking would be collected from US News and World Report
 - ii. Negative graduate program rankings would represent programs of lesser prestige than CMU
 - iii. Positive graduate program rankings would represent programs of greater prestige than CMU
 - c. Average Comparative Ranking by year (for whole sample and each of three sample years)

Whole Sample Descriptive Statistics					
	N	Minimum	Maximum	Mean	Std. Deviation

15. Distance of location/graduate institution location from Pittsburgh
 - a. This variable could help indicate how undergraduates found their experience in Pittsburgh
 - b. Percentages of the job locations (states) of CMU alumni
 - i. This variable would be calculated using the Career Center data on job location
