Bregman proximal methods for convex optimization

Javier Peña, Carnegie Mellon University

November 2019

About me and this lecture

I have been a professor at the Tepper School and interested in convex optimization for many years (since last millennium).

This lecture is based on the following paper (revision coming up):

https://arxiv.org/abs/1812.10198

Please tell everyone you know about it.

Nice complement to Convex Optimization:

47-860, Convex Analysis, MW 3:30-5:20pm, mini-3, 2020.

Preamble: (Euclidean) proximal methods

Composite convex minimization

Consider the problem

$$\min_{x \in \mathbb{R}^n} \left\{ f(x) + \psi(x) \right\}$$

where $f : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is differentiable and convex, and $\psi : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is closed and convex with $\operatorname{dom}(\psi) \subseteq \operatorname{dom}(f)$.

Let $Prox_t$ be the following *proximal map*

$$\operatorname{Prox}_t(x) := \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \frac{1}{2t} \|z - x\|^2 + \psi(z) \right\}.$$

Proximal gradient and accelerated proximal gradient

Consider the problem

 $\min_{x\in\mathbb{R}^n}{\{f(x)+\psi(x)\}}.$

Proximal gradient (PG)

pick
$$t_k > 0$$

 $x_{k+1} = \text{Prox}_{t_k}(x_k - t_k \nabla f(x_k))$

Accelerated proximal gradient (APG)

$$\begin{aligned} & \mathsf{pick} \quad \beta_k \geq 0, \ t_k > 0 \\ & y_k = x_k + \beta_k (x_k - x_{k-1}) \\ & x_{k+1} = \mathsf{Prox}_{t_k} (y_k - t_k \nabla f(y_k)) \end{aligned}$$

Choice of stepsize

Consider the generic update

$$z_{+} = \mathsf{Prox}_{t}(y - t\nabla f(y)).$$

Observe

$$\begin{split} & \operatorname{Prox}_t(y - t\nabla f(y)) \\ &= \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ f(y) + \langle \nabla f(y), z - y \rangle + \frac{1}{2t} \|z - y\|^2 + \psi(z) \right\}. \end{split}$$

It makes sense to choose t so that $z_+ = \mathsf{Prox}_t(y - t \nabla f(y))$ satisfies

$$f(z_+)+\psi(z_+)\leq f(y)+\langle \nabla f(y),z_+-y\rangle+\frac{1}{2t}\|z_+-y\|^2+\psi(z_+)$$
 or equivalently

$$f(z_+) - f(y) - \langle \nabla f(y), z_+ - y \rangle \le \frac{1}{2t} ||z_+ - y||^2.$$

Bregman distance and L-smoothness

The latter condition can be restated as

$$D_f(z_+, y) \le \frac{1}{2t} ||z_+ - y||^2$$

where D_f is the following *Bregman distance* generated by f

$$D_f(z,y) := f(z) - f(y) - \langle \nabla f(y), z - y \rangle.$$

L-smoothness

We say that f is L-smooth if for all $z, y \in dom(f)$

$$D_f(z,y) \le \frac{L}{2} ||z-y||^2.$$

In this case the condition at the top holds for t = 1/L.

Fact: f is L-smooth if ∇f is L-Lipschitz.

Convergence of PG

PG: solve $\min_x \{f(x) + \psi(x)\}$ via

$$x_{k+1} = \mathsf{Prox}_{t_k}(x_k - t_k \nabla f(x_k)).$$

Theorem

If the stepsizes t_k satisfy

$$D_f(x_{k+1}, x_k) \le \frac{1}{2t_k} \|x_{k+1} - x_k\|^2$$

then for all $\bar{x} \in \operatorname{argmin}_x\{f(x) + \psi(x)\}$ the PG iterates satisfy

$$f(x_k) + \psi(x_k) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{\|x_0 - \bar{x}\|^2}{2\sum_{i=0}^{k-1} t_i}.$$

In particular, if each $t_k \ge 1/L > 0$ then

$$f(x_k) + \psi(x_k) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{L \cdot ||x_0 - \bar{x}||^2}{2k}.$$

Convergence of APG

APG: solve
$$\min_x \{f(x) + \psi(x)\}$$
 via

$$y_k = x_k + \beta_k (x_k - x_{k-1})$$
$$x_{k+1} = \mathsf{Prox}_{t_k} (y_k - t_k \nabla f(y_k))$$

Theorem (Beck & Teboulle 2009, Nesterov 2013) Suppose $\beta_k = \frac{k-1}{k+2}$ and the stepsizes t_k satisfy $t_k \ge 1/L > 0$ and $D_f(x_{k+1}, y_k) \le \frac{1}{2t_k} ||x_{k+1} - y_k||^2$.

Then for all $\bar{x} \in \operatorname{argmin}_x\{f(x) + \psi(x)\}$ the APG iterates satisfy

$$f(x_k) + \psi(x_k) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{2L \cdot ||x_0 - \bar{x}||^2}{(k+1)^2}.$$

Main story: Bregman proximal methods

Proximal map again

Observe

$$\begin{split} & \operatorname{Prox}_t(x - t\nabla f(x)) \\ &= \operatorname*{argmin}_{y \in \mathbb{R}^n} \left\{ f(x) + \langle \nabla f(x), y - x \rangle + \frac{1}{2t} \|y - x\|^2 + \psi(y) \right\} \\ &= \operatorname*{argmin}_{y \in \mathbb{R}^n} \left\{ \langle \nabla f(x), y \rangle + \psi(y) + \frac{1}{2t} \|y - x\|^2 \right\}. \end{split}$$

Also get $\mathcal{O}(1/k)$ and $\mathcal{O}(1/k^2)$ convergence of proximal gradient methods when f is L-smooth:

$$D_f(y,x) \le \frac{L}{2} ||y-x||^2.$$

The above can be relaxed and extended.

Bregman proximal map

Let $h : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ be a diff. convex *reference* function.

The Bregman distance associated to h is

$$D_h(y,x) := h(y) - h(x) - \langle \nabla h(x), y - x \rangle.$$

This distance defines the following Bregman proximal map

$$g \mapsto \mathop{\mathrm{argmin}}_{y \in \mathbb{R}^n} \left\{ \langle g, y \rangle + \frac{1}{t} D_h(y, x) + \psi(y) \right\}$$

The previous *Euclidean* proximal map corresponds to the squared Euclidean norm reference function

$$h(x) = \frac{\|x\|^2}{2} \rightsquigarrow D_h(y, x) = \frac{\|y - x\|^2}{2}$$

What we just discussed for Euclidean proximal methods extends to Bregman proximal methods.

Bregman proximal gradient

Consider the problem

$$\min_{x \in \mathbb{R}^n} \{ f(x) + \psi(x) \},\$$

and suppose $h: \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is a reference function.

Bregman proximal gradient (BPG)

$$\begin{split} & \mathsf{pick} \ t_k > 0 \\ & x_{k+1} = \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \langle \nabla f(x_k), z \rangle + \frac{1}{t_k} D_h(z, x_k) + \psi(z) \right\} \\ & = \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ f(x_k) + \langle \nabla f(x_k), z - x_k \rangle + \frac{1}{t_k} D_h(z, x_k) + \psi(z) \right\} \end{split}$$

Accelerated Bregman proximal gradient (ABPG) (Gutman-P 2018)

Generate sequences x_k, y_k, z_k for k = 0, 1, ... as follows:

$$\begin{aligned} & \text{pick } t_k > 0 \\ & z_{k+1} = \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \langle \nabla f(y_k), z \rangle + \frac{1}{t_k} D_h(z, z_k) + \psi(z) \right\} \\ & x_{k+1} = \frac{\sum_{i=0}^k t_i z_{i+1}}{\sum_{i=0}^k t_i} \\ & y_{k+1} = \frac{\sum_{i=0}^k t_i z_{i+1} + t_{k+1} z_{k+1}}{\sum_{i=0}^{k+1} t_i} \end{aligned}$$

Related work by Hanzely-Richtarik-Xiao (2018).

Why use Bregman proximal methods?

- The Bregman proximal template provides a lot more flexibility.
- The additional freedom to choose h can facilitate the computation of the proximal mapping. For instance for $x \in \Delta_{n-1} := \{x \in \mathbb{R}^n_+ : \|x\|_1 = 1\}$ the map

$$g \mapsto \underset{y \in \Delta_{n-1}}{\operatorname{argmin}} \{ \langle g, y \rangle + D_h(y, x) \}$$

is simpler for $h(x) = \sum_{i=1}^{n} x_i \log(x_i)$ than for $h(x) = ||x||^2/2$.

• The usual *L*-smoothness assumption for convergence can be replaced by a *relative L*-smoothness that holds more broadly.

Example: D-optimal design problem (min-vol enclosing ellipsoid)

$$\min_{x \in \Delta_{n-1}} -\log(\det(HXH^{\mathsf{T}})))$$

where X = Diag(x) and $H \in \mathbb{R}^{m \times n}$ with m < n.

Example: Poisson linear inverse problem

 $\min_{x \in \mathbb{R}^n_+} D_{KL}(b, Ax)$

where $b \in \mathbb{R}^n_{++}$ and $A \in \mathbb{R}^{m \times n}_+$ with m > n and $D_{KL}(\cdot, \cdot)$ is the Kullback-Leibler divergence, that is, the Bregman distance associated to $x \mapsto \sum_{i=1}^n x_i \log(x_i)$.

We could tackle the above two problems via Euclidean proximal methods. However, they are more amenable to Bregman proximal methods with the *Burg entropy* reference function

$$h(x) = -\sum_{i=1}^{n} \log(x_i).$$

Convergence rates of proximal gradient methods

Bregman proximal gradient (BPG) Solve $\min_{x \in \mathbb{R}^n} \{f(x) + \psi(x)\}$ via

$$x_{k+1} = \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \langle \nabla f(x_k), z \rangle + \frac{1}{t_k} D_h(z, x_k) + \psi(z) \right\}$$

BPG convergence

BPG has $\mathcal{O}(1/k)$ convergence when f is smooth relative to h, that is, when

$$D_f(y,x) \le L \cdot D_h(y,x)$$

for all $x, y \in \operatorname{dom}(f)$.

Convergence rates of proximal gradient methods

Accelerated Bregman proximal gradient (ABPG) Solve $\min_{x\in\mathbb{R}^n}{\{f(x)+\psi(x)\}}$ via

$$z_{k+1} = \underset{z \in \mathbb{R}^n}{\arg\min} \left\{ \langle \nabla f(y_k), z \rangle + \frac{1}{t_k} D_h(z, z_k) + \psi(z) \right\}$$
$$x_{k+1} = \frac{\sum_{i=0}^k t_i z_{i+1}}{\sum_{i=0}^k t_i}$$
$$y_{k+1} = \frac{\sum_{i=0}^k t_i z_{i+1} + t_{k+1} z_{k+1}}{\sum_{i=0}^{k+1} t_i}$$

ABPG convergence

ABPG has convergence $\mathcal{O}(1/k^{\gamma})$ if f is (L, γ) -smooth relative to h. (To be defined soon.)

Fenchel duality

Convex conjugate

For $\phi: \mathbb{R}^n \to \mathbb{R}$ let $\phi^*: \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ be defined via

$$\phi^*(u) = \sup_{x \in \mathbb{R}^n} \{ \langle u, x \rangle - \phi(x) \}.$$

Consider the *primal* problem

$$\min_{x} \left\{ f(x) + \psi(x) \right\}.$$

The corresponding Fenchel dual problem is

$$\max_{u} \{-f^*(u) - \psi^*(-u)\}.$$

Observation If $f(\bar{x}) + \psi(\bar{x}) = -f^*(\bar{u}) - \psi^*(-\bar{u})$ then \bar{x} and \bar{u} are optimal.

An approach to show convergence

Suppose an algorithm generates sequences x_k, v_k, w_k such that

$$f(x_k) + \psi(x_k) \le -f^*(v_k) - \psi^*(w_k) - d_k^*(-v_k - w_k)$$

for some sequence of "distance" functions $d_k : \mathbb{R}^n \to \mathbb{R}$. Then for all $\bar{x} \in \operatorname{argmin}_x \{f(x) + \psi(x)\}$ we have

$$f(x_k) + \psi(x_k) - (f(\bar{x}) + \psi(\bar{x})) \le d_k(\bar{x}).$$

Punchline

For suitable t_k the BPG and ABPG iterates satisfy the above for

$$d_k(z) = \frac{1}{\sum_{i=0}^k t_i} D_h(z, z_0).$$

A key lemma for Bregman proximal methods

Suppose $y_k, z_k \in {\rm ri}({\rm dom}(h)) \cap {\rm dom}(\psi), g_k := \nabla f(y_k),$ and $t_k > 0$ satisfy

$$z_{k+1} = \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \langle g_k, z \rangle + \frac{1}{t_k} D_h(z, z_k) + \psi(z) \right\}$$
for $k = 0, 1, 2, \dots$

Via the optimality conditions rewrite above as

$$g_k + g_k^{\psi} + \frac{1}{t_k} (\nabla h(z_{k+1}) - \nabla h(z_k)) = 0$$

for some $g_k^{\psi} \in \partial \psi(z_{k+1})$.

A key lemma for Bregman proximal methods Let

$$v_k := \frac{\sum_{i=0}^{k} t_i g_i}{\sum_{i=0}^{k} t_i}, \ w_k := \frac{\sum_{i=0}^{k} t_i g_i^{\psi}}{\sum_{i=0}^{k} t_i}$$

Lemma

Suppose $y_k, z_k, g_k, g_k^{\psi}, t_k$ and v_k, w_k are as above. Then

$$\frac{\sum_{i=0}^{k} t_i(f(z_{i+1}) + \psi(z_{i+1}) - D_f(z_{i+1}, y_i)) + D_h(z_{i+1}, z_i)}{\sum_{i=0}^{k} t_i}$$

$$= -\frac{\sum_{i=0}^{k} t_i(f^*(g_i) + \psi^*(g_i^{\psi}))}{\sum_{i=0}^{k} t_i} - d_k^*(-v_k - w_k)$$

$$\leq -f^*(v_k) - \psi^*(w_k) - d_k^*(-v_k - w_k)$$

where

$$d_k(z) := \frac{1}{\sum_{i=0}^k t_i} D_h(z, z_0).$$

Bregman proximal gradient (BPG)

In this case

$$x_{k+1} = \underset{z \in \mathbb{R}^n}{\operatorname{argmin}} \left\{ \langle \nabla f(x_k), z \rangle + \frac{1}{t_k} D_h(z, x_k) + \psi(z) \right\}$$

Theorem (Gutman-P 2018) Suppose each t_i is such that

$$D_f(x_{i+1}, x_i) \le \frac{1}{t_i} D_h(x_{i+1}, x_i).$$
 (DC)

Then for $\bar{x} \in \underset{x \in \mathbb{R}^n}{\operatorname{argmin}} \{f(x) + \psi(x)\}$ the BPG iterates satisfy

$$f(x_{k+1}) + \psi(x_{k+1}) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{1}{\sum_{i=0}^{k} t_i} D_h(\bar{x}, x_0).$$

Proof of Theorem.

In this case we can apply Lemma to $x_k = y_k = z_k$ and get

$$\frac{\sum_{i=0}^{k} t_i(f(x_{i+1}) + \psi(x_{i+1}) - D_f(x_{i+1}, x_i)) + D_h(x_{i+1}, x_i)}{\sum_{i=0}^{k} t_i} \le -f^*(v_k) - \psi^*(w_k) - d_k^*(-v_k - w_k).$$

Next, (DC) implies

$$f(x_{k+1}) + \psi(x_{k+1}) \le \frac{\sum_{i=0}^{k} t_i(f(x_{i+1}) + \psi(x_{i+1}))}{\sum_{i=0}^{k} t_i} \le -f^*(v_k) - \psi^*(w_k) - d_k^*(-v_k - w_k).$$

Thus for all $\bar{x} \in \mathrm{argmin}_{x \in \mathbb{R}^n} \{f(x) + \psi(x)\}$

$$f(x_k) + \psi(x_k) \le f(\bar{x}) + \psi(\bar{x}) + \frac{1}{\sum_{i=0}^k t_i} D_h(\bar{x}, x_0).$$

24 / 35

Relative smoothness

Suppose f, h are convex and differentiable on Q. We say that f is L-smooth relative to h on Q if for all $x, y \in Q$

$$D_f(y,x) \le LD_h(y,x).$$

(Nguyen 2012, Bauschke et al. 2017, Lu et al. 2018)

If f is L-smooth relative to h on dom(ψ) then (DC) holds for $t_i = 1/L, i = 0, 1, \dots, k-1$ and BPG iterates satisfy

$$f(x_k) + \psi(x_k) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{LD_h(\bar{x}, x_0)}{k}.$$

Recover results by Bauschke-Bolte-Teboulle (2017) and by Lu-Freund-Nesterov (2018).

This extends the $\mathcal{O}(1/k)$ convergence rate of PG.

Accelerated Bregman proximal gradient (ABPG)

Generate sequences x_k, y_k, z_k as follows:

$$\begin{aligned} z_{k+1} &= \operatorname*{argmin}_{z \in \mathbb{R}^n} \left\{ \langle \nabla f(y_k), z \rangle + \frac{1}{t_k} D_h(z, z_k) + \psi(z) \right\} \\ x_{k+1} &= \frac{\sum_{i=0}^k t_i z_{i+1}}{\sum_{i=0}^k t_i} \\ y_{k+1} &= \frac{\sum_{i=0}^k t_i z_{i+1} + t_{k+1} z_{k+1}}{\sum_{i=0}^{k+1} t_i}. \end{aligned}$$

By letting $\theta_k := \frac{t_k}{\sum_{i=0}^k t_i}$ the last two equations can be rewritten as

$$x_{k+1} = (1 - \theta_k)x_k + \theta_k z_{k+1}$$

$$y_{k+1} = (1 - \theta_{k+1})x_{k+1} + \theta_{k+1} z_{k+1}$$

$$= x_{k+1} + \frac{\theta_{k+1}(1 - \theta_k)}{\theta_k} (x_{k+1} - x_k)$$

Accelerated Bregman proximal gradient (ABPG) Theorem (Gutman-P 2018)

Suppose each t_i and θ_i are such that

$$D_f(x_{i+1}, y_i) - (1 - \theta_i) D_f(x_i, y_i) \le \frac{\theta_i}{t_i} D_h(z_{i+1}, z_i).$$
 (ADC)

Then for $\bar{x}\in\bar{X}:=\operatorname*{argmin}_{x\in\mathbb{R}^n}\{f(x)+\psi(x)\}$ the ABPG iterates satisfy

$$f(x_{k+1}) + \psi(x_{k+1}) - (f(\bar{x}) + \psi(\bar{x})) \le \frac{1}{\sum_{i=0}^{k} t_i} D_h(\bar{x}, x_0).$$

Proof.

Similar to previous one for BPG: use lemma & Fenchel duality.

Compare (ADC) condition for ABPG with (DC) condition for BPG:

$$D_f(x_{i+1}, x_i) \le \frac{1}{t_i} D_h(x_{i+1}, x_i).$$
 (DC)

Relative smoothness revisited

How much can we accelerate?

Choose $t_k > 0$ or equivalently $\theta_k = \frac{t_k}{\sum_{i=0}^k t_i}$ as large as possible so that (ADC) holds. How large can we choose it?

(L,γ) relative smoothness

Say that f is $(L,\gamma)\text{-smooth}$ relative to h on Q if for all $x,y,z,\tilde{z}\in Q$ and $\theta\in[0,1]$

$$D_f((1-\theta)x+\theta\tilde{z},(1-\theta)x+\theta z) \le L\theta^{\gamma}D_h(\tilde{z},z).$$

Observe

In Euclidean case $L\mbox{-relative smoothness yields } (L,2)\mbox{-relative smoothness.}$ In general this does not hold but "almost"...

Accelerated Bregman proximal gradient

Theorem (Gutman-P 2018)

Suppose f is (L, γ) -smooth relative to h on $ri(dom(h)) \cap dom(\psi)$ for some L > 0 and $\gamma > 0$.

Then the stepsizes t_k can be chosen so that the ABPG iterates satisfy

$$f(x_{k+1}) + \psi(x_{k+1}) - (f(\bar{x}) + \psi(\bar{x})) \le \left(\frac{\gamma}{k+\gamma}\right)^{\gamma} LD_h(\bar{X}, x_0).$$

Recover iconic $\mathcal{O}(1/k^2)$ rate when $h(x) = \frac{1}{2} ||x||^2$ and f is *L*-smooth.

Accelerated Bregman proximal gradient

For implementation purposes: pick $\theta_k = \frac{t_k}{\sum_{i=0}^k t_i}$ as large as possible so that (ADC) holds. Pick θ_k of the form

$$\theta_k = \frac{\gamma_k}{k + \gamma_k}$$

via backtracking on $\gamma_k.$ If all $\gamma_k \geq \gamma > 0$ then we get

$$f(x_{k+1}) + \psi(x_{k+1}) - (f(\bar{x}) + \psi(\bar{x})) \le \left(\frac{\gamma}{k+\gamma}\right)^{\gamma} LD_h(\bar{X}, x_0).$$

If we can do the above with $\gamma = 2$ we recover $O(1/k^2)$ rate. This happens when $h(x) = \frac{1}{2} ||x||^2$.

Numerical experiments

BPG-LS and ABPG-LS implementations

- Line-search to choose t_k in BPG so that (DC) holds.
- Likewise for t_0 and $\theta_k \in (0,1)$ in ABPG to ensure (ADC).
- Pick $\theta_k \in (0,1)$ of the form $\theta_k = \frac{\gamma_k}{k + \gamma_k}$.

ABPG: use educated guess for t_0 and $\theta_k=2/(k+2).$

Problem instances

- D-optimal design: $\min_{x \in \Delta_{n-1}} -\log(\det(HXH^{\mathsf{T}}))$
- Poisson linear inverse: $\min_{x \in \mathbb{R}^n_+} D_{KL}(b, Ax)$

In both cases use reference function

$$h(x) = -\sum_{i=1}^{n} \log(x_i).$$

Bregman proximal mappings are easily computable in both cases.

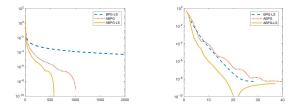

Figure: Suboptimality gap for 100×250 and 200×300 random instances of D-optimal design.

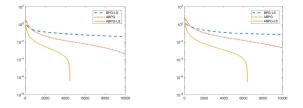

Figure: Suboptimality gap for 250×100 and 300×200 random instances of the Poisson linear inverse problem.

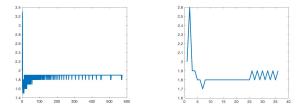

Figure: Sequence $\{\gamma_k : k = 1, 2, ...\}$ in ABPG-LS for typical instances of D-design optimal problem.

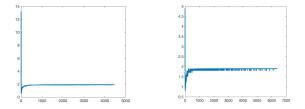

Figure: Sequence $\{\gamma_k : k = 1, 2, ...\}$ in ABPG-LS for typical instances of Poisson linear inverse problem.

Conclusions

• Analysis of Bregman proximal methods via Fenchel duality. Key observation: algorithms generate x_k, v_k, w_k such that

 $f(x_{k+1}) + \psi(x_{k+1}) \le -f^*(v_k) - \psi^*(w_k) - d_k^*(-v_k - w_k).$

- Other related developments that we did not discuss:
 - Proximal subgradient method when f is non-differentiable
 - Linear convergence via restarting
 - Analogous results for conditional gradient
- Current/future work
 - Saddle-point problems
 - Stochastic first-order methods
 - More computational experiments
 - Role of γ in accelerated Bregman proximal methods
